

Figure 3. (a) Only removing the decision-simulation layer moves the objective (95% CI shown); the other four removals are exactly 0.000 (significance not assessed). (b) Neutralising the optimizer's risk-penalty term ($\lambda = 0$) recovers most of the lost metric; the risk manager is decisive in 75% of pairs (35 improved / 0 degraded / 10 neutral), with 0/390 risk-score transmission errors. $\lambda = 0$ is a diagnostic intervention within the deterministic architecture — not a production recommendation and not causal evidence. Synthetic.
